WHAT IS A TOKEN?

A token is a kernel object that caches part of a user's security profile, including the user SID, group SIDs, and privileges ([WhatIsAPrivilege](#)). [WhatIsSecurityContext](#) discusses the basics of how this cache is normally used, but there's a bit more to it: A token also holds a reference to a logon session ([WhatIsALogonSession](#)) and a set of default security settings that the kernel uses.

Tokens are propagated automatically as new processes are created. A new process naturally inherits a copy of the parent's process token. Even if the thread that creates the process is impersonating, the new process gets a copy of the parent's process token, not the thread token, which usually surprises most people who are new to impersonation ([WhatIsImpersonation](#)). If you want to start a new process running with some other token, see [HowToRunAProgramAsAnotherUser](#).

BY THIS DEFINITION, DO WE NEED TO REVIEW OUR CLUB NAME?
